On the role of local matching for efficient semi-supervised protein sequence classification (Kuksa, Huang and Pavlovic)

Outline

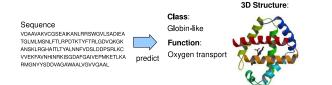

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ● □ ■ ● ● ●

Introduction: problem formulation

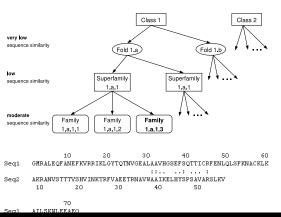

- Task: sequence classification in the remote similarity setting
- Goal: classify / group sequences together when basic content of sequences within class very diverse ⇒ rely on very *sparse invariant* (preserved) features
- problems occur in many different domains e.g. text, music, etc.
- focus on biological sequences
 - infer functional properties from *primary sequence only* important (inexpensive)
 - a challenging computational and modeling problem

Introduction: problem formulation (Cont'd)

- Protein sequences: *linear* strings of amino acids ($|\Sigma| = 20$)
- Goal: accurately predict superfamily of unknown sequences
- SCOP (Structural Classification of Proteins [6]) hierarchy

- remote homology means superfamily
- Challenges:
 - primary sequence
 - Iow similarity
 - variable-length
- focus on methods that are
 - sparse (will motivate)

interpretable

Previous state-of-the-art methods

- mismatch(k,m) kernel [4]: map sequences into k-mer space; similarity defined on *inexact match* of *observed* k-mers for up to m mismatches (induced features have exponential size)
- Sparse spatial sample kernel (SSSK) [3]: map sequences into multi-resolutional sampling space. Inexact matching accomplished using variable-length substrings carrying don't-care characters

(ロ) (同) (三) (三) (三) (三) (○)

Semi-supervised Learning

• Few positive and many negative training sequences: leads to sub-optimal classification performance. Both string kernels overcome such problem using *unlabeled* sequences under the semi-supervised learning framework and show very promising results [2, 7]. The new fixed-length representation of a sequence *X* takes the following form:

$$\Phi^{new}(X) = \frac{1}{|N(X)|} \sum X' \in N(X) \Phi orig(X'), \quad (1)$$

which implies the following kernel form:

$$K(X,Y) = \sum X' \in N(X) \sum Y' \in N(Y) \frac{K(X',Y')}{|N(X)||N(Y)|},$$
(2)

where N(X), N(Y) the *neighborhood* of sequences X and Y in the unlabeled dataset ($N(X) = \{X' : s(X, X') \le \delta\}$, s(.) a scoring function, *e.g.* e-Value).

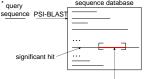

Issues and our proposed methods:

Uncurated unlabeled sequence databases are noisy:

• Abundant long, multi-domain sequences that may contain irrelevant sub-sequences compromising quality of classifiers. (Solution: *Extract* **regions** *from neighboring sequences that are most likely to be biologically relevant.*

$$R(X) = \{x' : s(X, X') \le \delta\},\$$

where $x' \sqsubseteq X'$ the most statistically significant matching region of an unlabeled neighbor X'.

statistically significant region

Abundant (near-)replicated sequences: cause the *averaged* estimate biasing towards over-represented sequences. (Solution: Cluster R(X) to obtain R^{*}(X) to remove such bias.)

Methods under comparison and evaluation

- Methods under comparison:
 - Unfiltered: Use N(X) and $N^*(X)$
 - 2 Region: Use R(X) and $R^*(X)$
 - on tails: Remove sequences that are too long or too short (give mathematical definition here).
 - *max length*: Remove neighbors whose length is greater than 250 (proposed by Weston *et al.* in [7] for convergence)
- Evaluation method: ROC50 [1] scores, the (normalized) area under the ROC curve computed for *up to* 50 false positives

Settings

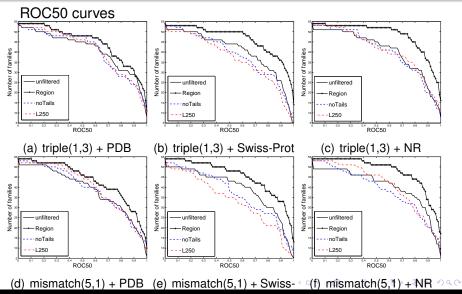

• use $K'(X, Y) = \frac{K(X,Y)}{\sqrt{K(X,X)K(Y,Y)}}$ to remove dependencies between the kernel values and sequence lengths

• use SPIDER¹ for SVMs; linear kernel, default parameters

- use PDB (small size) Swiss-Prot (moderate size) and non-redundant (large size) sets as unlabeled databases
- neighborhood N(X) for each sequence X (train + test) $N(X) = \{X' : eValue(X, X') \le 0.05\}$ with 2 PSI-BLAST iterations
- Clustering *R*(*X*) and *N*(*X*) done using the program CD-Hit [5] at 70% similarity level.

On the role of local matching for efficient semi-supervised protein sequence classification (Kuksa, Huang and Pavlovic)

◆□▶ ◆□▶ ◆□▶ ◆□▶ ●□□ のQ@

Comparison with other state-of-the-art methods

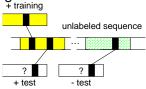

Table: Comparison of performance (ROC50) against the state-of-the-art methods.

method	PDB	Swiss-Prot	NR
triple(1,3)	.7582	.6908	.7327
triple(1,3), region	.8265	.8556	.8861
triple(1,3), region, clustering	.8246	.8605	.8944
mismatch(5,1)	.7203	.6685	.7233
mismatch(5,1), region	.8048	.8280	.8824
mismatch(5,1), region, clustering	.8038	.8414	.8885
profile(5,7.5)	.7205	.7914	.8151

- Number of PSI-BLAST iterations: two
- Region-based method with clustered neighborhood demonstrated the best performance in almost every case.
- ROC50 scores of triple and mismatch kernels *strongly outperform* those of the profile kernel.

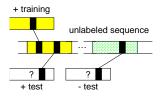

The importance of region extraction

- yellow (shaded): positive, green (pattern) negative, arcs: (possibly weak) similarity induced by shared features (black boxes) and absence of arcs indicates no similarity
- Goal: infer membership of the test (unshaded) sequences via the unlabeled sequences (middle).
- Positive training and test sequences share no features and hence no similarity. The unlabeled sequence, which shares features with both sequences, establishes the similarity.
- However, if matching is global, then the unlabeled sequence might also establish the similarity between the positive training and negative test sequences. = → = = →

The importance of region extraction: an example

 In Swiss-Prot, Sequence Q62059 is multi-domain. The domains belongs to different folds (one level higher than superfamily). ROC50 scores without region extraction are .3250 and .3292 for triple and mismatch. ROC50 scores with region extraction improve to .9464 and .9664.

(ロ) (同) (三) (三) (三) (三) (○)

Key Contributions

- motivation: sequences in remotely similar setting; only very few positions invariant
- sparse profile HMM: recovers critical positions but some not unique to superfamily: need discriminative models
- logistic classifier + sparsity-enforcing priors recover unique critical positions and the preferred residues; achieve state-of-the-art, but need sub-string comparison and semi-supervised learning for better improvement
- systematic and biologically motivated approach for semi-supervised training + a sparse string kernel: strongly outperforms state-of-the-art methods and also recovers some *critical patterns*
- All presented methods can be applied to a wide range of applications (music, word utterance recognition, text document classification, ··· etc.)

Future work

- still room for improvement; notice some hard to classify superfamilies
- joint training / feature sharing framework to recover (or exploit) tree hierarchy in sequences (have some preliminary results)
- general sequence classification: music, text documents, word utterance, ··· etc.
